Chapter 1

Introduction and Scenario

1.1 Scenario Choice

This project follows **Scenario C - Omnichannel Commerce Core**. VerdeMart Retail started by using nopCommerce as its online storefront, but the business now needs more than a web shop. It wants web sales, warehouse execution, shipping, store operations, support, and customer visibility to work together as part of one commerce experience.

In this scenario, nopCommerce becomes the commerce core of that wider ecosystem. A web order should be reflected in operational systems such as warehouse and shipping, and changes that happen outside nopCommerce, such as stock or fulfillment updates, should become visible again in the customer and operator experience. This is important because those surrounding systems may be slow, stale, unavailable, or inconsistent, but the commerce experience still needs to remain useful and understandable.

1.2 Core Architectural Problem

Currently, nopCommerce mainly acts as the online shop: it owns the storefront, catalog browsing, cart, checkout, customer accounts, and order creation inside one web-centered platform. This works while the business is mostly operating through the online channel, but it does not fully address an omnichannel environment where warehouse execution, shipping, store operations, and support systems also influence the customer experience.

The core architectural problem is deciding how this online shop can evolve into a commerce core without assuming that every surrounding operational system is always fast, available, and consistent. The architecture must define what remains inside nopCommerce, what moves around it, and how the system behaves when warehouse or shipping state is delayed, stale, unavailable, or later recovered.

Chapter 4

Quality Attribute Scenarios

Quality attribute scenarios make the architectural drivers measurable. For the VerdeMart omnichannel scenario, the most important pressure is not only that nopCommerce must create orders correctly, but that the commerce experience must remain understandable while warehouse, shipping, store, and support systems are slow, stale, unavailable, or later recovering.

The scenarios below use the six-part structure from the course material: stimulus source, stimulus, artifact, environment, response, and response measure.

4.1 Architectural Drivers

The scenarios are driven by four architectural concerns:

- **Availability:** web orders must not be lost when warehouse or shipping systems fail.
- **Consistency:** inventory and order state may be temporarily stale, but inconsistencies must be visible and recoverable.
- **Performance:** customer-facing operations must stay responsive during backend synchronization and sales peaks.
- **Modifiability:** new operational channels must be integrated without rewriting checkout or sharing the nopCommerce database.

4.2 Scenario 1 - Availability under Warehouse Failure

Driver: Availability and operational continuity.

Part	VerdeMart scenario
Stimulus source	Warehouse execution system
Stimulus	The warehouse API takes more than 10 seconds to respond or rejects fulfillment requests for newly paid web orders.
Artifact	Fulfillment synchronization and the order status view shown to customers and operators
Environment	Friday afternoon peak traffic, with 3 times normal order volume, while the warehouse dependency is degraded but the web shop is still accepting orders
Response	The order is accepted and persisted locally; the fulfillment request is stored for asynchronous retry; the order is shown as awaiting warehouse confirmation; subsequent orders are not blocked by the degraded dependency.
Response measure	No paid order is lost; no duplicate fulfillment request is sent; pending fulfillment state is visible to support within 30 seconds; retry or escalation starts within 5 minutes.

4.3 Scenario 2 - Consistency under Stale Inventory

Driver: Consistency and recoverable inventory state.

Part	VerdeMart scenario
Stimulus source	Store point-of-sale system and warehouse stock service
Stimulus	A store sale reduces stock by 5 units, but the update reaches nopCommerce 3 minutes after the web catalog still showed those units as available.
Artifact	Inventory availability view used by product pages, cart validation, and checkout
Environment	Concurrent web and physical-store sales for the same product during a promotion, with external stock updates delayed by up to 3 minutes
Response	The commerce core marks stock data as stale, revalidates stock before checkout completion, preserves already-created orders for reconciliation, and records an inventory discrepancy for recovery.
Response measure	Product pages show stale stock status within 30 seconds of detection; overselling stays under 1% of affected order lines; inventory discrepancies are queued for reconciliation within 1 minute.

4.4 Scenario 3 - Performance during Omnichannel Order Bursts

Driver: Performance under customer-facing load.

Part	VerdeMart scenario
Stimulus source	Web customers, store operators, and customer support agents
Stimulus	A campaign creates 5 times normal traffic for product browsing, cart validation, order creation, and order-status queries.
Artifact	Storefront, checkout path, order status view, and integration event publishing path
Environment	Peak campaign period, with 5 times normal traffic and background synchronization still running
Response	The system prioritizes checkout writes, serves order-status reads from a projection, and processes warehouse and shipping synchronization asynchronously without blocking the customer request path.
Response measure	Checkout p95 latency remains below 2 seconds; order-status read p95 remains below 1 second; at least 99% of integration events are published or queued within 60 seconds.

4.5 Scenario 4 - Recoverability after Shipping Outage

Driver: Recoverability after external dependency failure.

Part	VerdeMart scenario
Stimulus source	Shipping provider or shipping adapter
Stimulus	Shipment label creation fails for 50 ready-to-dispatch orders and later becomes available again.
Artifact	Shipping integration workflow, retry queue, and order shipment status
Environment	Warehouse has packed orders, but the external shipping provider is unavailable for 20 minutes
Response	The system stores failed label requests, keeps orders in a clear awaiting-shipping state, avoids repeated synchronous calls from operators, and resumes processing automatically when the provider recovers.
Response measure	100% of failed label requests are retained; operators see the outage state within 30 seconds; 95% of queued labels are created within 10 minutes after provider recovery.

4.6 Scenario 5 - Modifiability for New Operational Channels

Driver: Modifiability and controlled integration growth.

Part	VerdeMart scenario
Stimulus source	VerdeMart business team and integration developers
Stimulus	A new store-operations system must receive order-ready-for-pickup events and send pickup-completed updates back to the commerce core.
Artifact	Integration layer, domain events, and order status update boundary
Environment	Existing web, warehouse, and shipping integrations are already in production
Response	The architecture allows the new channel to be added through a new adapter and event subscription without changing checkout logic or sharing the nopCommerce database with the external system.
Response measure	The new integration requires changes in no more than one adapter and one application-service boundary; no direct external database access is introduced; regression tests for checkout and existing integrations remain green.

4.7 Traceability to Architectural Drivers

Scenario	Architectural driver
Availability under warehouse failure	Availability, recoverability
Consistency under stale inventory	Consistency
Performance during omnichannel order bursts	Performance
Recoverability after shipping outage	Recoverability, availability
Modifiability for new operational channels	Modifiability
